## Experimental setting (train epoch, model parameter, etc.)

After building the model aligned with the assignment specification, I trained the model with the default setting provided by the TAs (`e_hidden`, `d_hidden` = 500; `epoch` = 20). However, the model seemed to mis-classify some numbers without any pattern. Thus, I concluded that this misclassification came from under-fitting.

Thereby, I increased the model's epoch to 200. As a result, the model produced lesser number of incorrect labels than the first trial did. However, I discovered a pattern that this model can not distinguish the labels with similar shape, meaning the model is still underfitted.

Lastly, I increased the model's epoch to 500 in order to prevent underfitting. I also refined `e_hidden` and `d_hidden` to 256 so as to prevent overfitting. The result as a success that I was able to observe few misclassifications.

5 Reconstruction images per each class.

Visualization of the 2D latent space.
